Appendix A. Supplementary Tables and Figures

Table A1.

Percentage of Students in the 2015 and 2016 High School Completion Cohorts Who Completed High School Within Six Years

| Coursetaking profile | Percentage who completed high school within six years |
|--------------------------|---|
| DE-only takers | 13% |
| DE takers with CTE focus | 1% |
| DE and AP/IB takers | 1% |
| AP/IB takers, no DE | 4% |
| CTE focus only | 4% |
| No acceleration | 38% |
| All students | 17% |

Note. Results based on whether students graduated from high school or earned an associate or bachelor's degree within six years from their expected high school completion.

Table A2.

Accelerated Coursework by High School Completion Cohort

| | High school completion cohort | | |
|---------------------------------|-------------------------------|----------------|----------------|
| | 2015 and 2016 (combined) | 2019 | 2022 |
| Dual enrollment | | | |
| None | 81% | 78% | 78% |
| 1 to 8 credits | 7% | 7% | 7% |
| 9 to 14 credits | 5% | 5% | 4% |
| 15 or more credits | 8% | 10% | 11% |
| AP/IB courses | | | |
| None | 60% | 57% | 57% |
| At least one course | 40% | 43% | 43% |
| High school CTE courses | | | |
| 0 to 4 courses | 32% | 26% | 24% |
| 5 to 9 courses | 38% | 34% | 32% |
| 10 or more courses | 30% | 40% | 44% |
| Total number of students | 661,558 | 362,273 | 374,515 |

A difference is statistically significant if its confidence interval does not overlap with zero percent.

Appendix B. Regression-Adjusted Analyses: Methods, Estimates, and Limitations

For research questions focused on understanding the link between students' accelerated coursetaking profiles and their college and earnings outcomes, we use regression analysis to include a host of statistical controls. The regression analyses presented in the main report were performed as we describe below.

Regression Analysis Methodology

Using student-level data on Texas public high school students from the 2015 and 2016 completion cohorts, we estimate the following regression using Ordinary Least Squares (OLS):

$$Y_{it} = \beta CourseProfile_i + \beta_1 \chi_i + \beta_2 TestScores_i + \alpha_{hs} + v_i \quad (1)$$

In this equation, Y_{it} is the outcome of the student i in year t from expected high school completion; $CourseProfile_i$ represents a vector of dummies for each of the college-and-career-accelerated coursework categories, excluding AP/IB takers with no DE, and B represents the four-point estimates from each category. χ_i represents a vector of student characteristics, namely student gender, low-income status, high school entry cohort, and race/ethnicity; $TestScores_i$ represents the student standardized TAKS math and reading test scores and the student ranking in the high school based on TAKS (top 10 percent and top 11th to 30th percent). When a test score was missing, we replaced it with the lowest test score in the student school and cohort and created a dummy equal to one when the missing test score value is imputed, which we included in the regression. We also control for high school fixed effects, α_{hs} , which capture time-invariant unobserved high school characteristics among the students in these two cohorts. v_i captures estimated robust standard errors. The high school fixed effect effectively controls for high school rurality and high school Title I status, as these are also time-invariant features for the cohorts. For simplicity, we refer to the high school fixed effects as high school characteristics in the report.

We use equation (1) to estimate differences in students' highest postsecondary attainment and average quarterly earnings across college-and-career-accelerated coursework profiles. For the attainment analysis, we constructed a set of dummy variables as the outcome, each equal to one if the student's highest credential corresponded to a specific attainment level. For example, if a student's highest credential is an associate degree, the corresponding outcome variable equals one; otherwise, it equals zero. For the earnings analysis, the outcome variable is the natural logarithm of students' non-zero quarterly earnings.

Our regression-adjusted estimate allows us to capture differences in post-high-school outcomes associated with students' participation in specific accelerated coursework profiles. The controls in our regressions account for factors shared by students with the same gender, race/ethnicity, socioeconomic background, standardized test scores, and within-high-school rankings. Additionally, high school fixed effects capture time-invariant characteristics at the school level. However, unobserved self-selection may still exist among students who attend the same high school and have similar demographic and test score profiles but who differ in their choice of accelerated coursework due to factors not captured in the data—such as access to external information about the value

of accelerated coursework or differences in advising received by students with otherwise similar characteristics. This means we cannot isolate unobserved factors that may influence both selection into these profiles and students' post-high-school outcomes. As a result, our findings should not be interpreted as the causal effects of accelerated coursework or as the returns to specific coursetaking profiles.

Regression-Adjusted Postsecondary Attainment Estimates

Table B1 shows the OLS estimation results of highest postsecondary attainment. The point estimates should be multiplied by 100 and be interpreted as percentage point differences in the probability of degree attainment relative to AP/IB takers with no DE (the reference group). For a discussion about these results and their implications, see the main report.

Table B1.

Estimates of the Relationship Between Coursetaking Profile and Highest Postsecondary Attainment by Sixth Year Post High School, 2015 and 2016 High School Completion Cohorts (Combined)

| | Never enrolled | Highest award is certificate | Highest award is associate | Highest award is bachelor's |

Regression-Adjusted Earnings Estimates

Table B2 shows the full OLS estimates using the natural logarithm of yearly non-zero average quarterly earnings as the outcome. We display the results for all students in the 2015 and 2016 cohorts used in Figure 8 of the main report for illustration purposes, as the same analyses are conducted for the student subgroup results. By taking the logarithm of the earnings, we interpret the point estimates as percentage changes relative to the change in the variable when multiplied by 100. For example, students who took advanced coursework had earnings in the first year post high school that were 10.6% higher than the earnings of AP/IB takers with no DE.

Limitations: Potential Attrition Bias in Earnings Difference Estimates

One important limitation of the earnings analysis is the attrition in earnings data due to unreported income. Unreported earnings appear as quarters without earnings, which may occur due to unemployment, earnings exempt from reporting, or working outside of the state of Texas. The data also exclude earnings from tips, military service, federal agency employment, and certain types of jobs not covered by unemployment insurance reporting, such as independent contracting or domestic work below specific earnings thresholds. As a result, we cannot distinguish between individuals who are unemployed, those who are employed but whose earnings are not reported, and those who are employed out of state.

Foote and Stange (2022) show that this type of attrition bias, particularly due to interstate migration, can affect estimates based on in-state administrative earnings data. However, both Foote and Stange (2022) and Andrews et al. (2016) find that this bias is relatively small in Texas compared with other states. Foote and Stange (2022) recommend that researchers mitigate this bias by conditioning analyses on non-zero earnings—an approach we adopt in this report.

However, attrition bias may look different across coursetaking profiles, which can have implications for our analysis. Table B3 shows the percentage of students in the 2015 and 2016 high school completion cohorts with non-zero reported earnings, both overall and by coursetaking profile. About 70% of students have reported earnings in the first, third, and sixth years after high school. However, students with no accelerated coursework are less likely than the other groups to have reported earnings—68%, 69%, and 65% have reported earnings in the first, third, and sixth years, respectively. In contrast, DE students with a CTE focus are more likely to have reported earnings—75%, 78%, and 78% in those same years.

To account for student and high school characteristics associated with this attrition bias, we use equation (1) to estimate the likelihood of having reported earnings, conditional on those characteristics. The outcome variables are indicators for the presence of reported earnings in years one, three, or six post expected high school completion. Results are shown in Table B4. Overall, DE students are between 1 and 3 percentage points more likely

to have non-zero earnings in the sixth year after high school than AP/IB students without DE. Students with a CTE focus only are similarly likely to have reported earnings as AP/IB students without DE (a 0.4-percentage-point difference). Students without any accelerated coursework exhibit the highest attrition, being 5.2 percentage points less likely to have reported earnings than AP/IB students without DE, and 8 percentage points less likely than students who took both DE and AP/IB courses.

Taken together, these results suggest that the earnings gaps among AP/IB students, DE takers, and CTE-focused students are subject to relatively small bias due to unreported earnings. However, students with no accelerated coursework are significantly less likely to have reported earnings than the other groups. If it is reasonable to assume that unreported earnings for these students are even lower than what is observed in the in-state reported earnings records, then the size of the gaps is likely underestimated. Conversely, if unreported earnings are higher—for example, if these students moved out of state to secure a high-paying job—then we could be overestimating the earnings gap for this group. Overall, this suggests that earnings results, particularly for students with no accelerated coursework, should be interpreted with caution.

Table B3.

Percentage of Students With Non-Zero Quarterly Earnings Reported by Coursetaking Profile, 2015 and 2016 High School Completion Cohorts (Combined)

| Coursetaking profile | Non-zero quarterly earnings | | |
|--------------------------|-----------------------------|------------|------------|
| | First year | Third year | Sixth year |

Regression-Adjusted Earnings by Highest Postsecondary Attainment

One mechanism through which college-and-career-accelerated coursework can increase earnings is by increasing postsecondary credential attainment, which enables students to obtain higher paying jobs. But even among students with the same educational attainment, accelerated coursework may increase earnings by enabling them to complete college sooner and gain more years of workplace experience; this study shows that students who took dual enrollment alone or in combination with AP/IB and CTE were more likely to earn a credential within three years post high school, indicating a shortened time to degree. Accelerated courses may also increase earnings by increasing human capital; for example, DE students may learn valuable skills that non-DE students with the same degree attainment do not obtain. We build on the prior OLS regression analyses to explore these issues. We estimate regression models among separate subgroups of students with the same credential attainment by year five. These estimates are presented in the figures in the main report of regression-adjusted average quarterly earnings by highest postsecondary attainment in the sixth year after expected high school completion. Table B5 shows the full regression results, for each attainment group, among students in the 2015 and 2016 high school completion cohorts.

CCRC studies community colleges because they provide critical access to postsecondary education and are uniquely positioned to promote equity and social mobility in the United States. Our mission is to conduct research that helps these institutions strengthen opportunities and improve outcomes for their students, particularly those from underserved populations.
